

End-to-End IT Service Catalog & Fulfillment Workflow

ServiceNow Portfolio Project | Personal Developer Instance (PDI) | Marcis Denzon Malabanan

Problem

New-hire IT provisioning at a small company was handled through ad-hoc emails and Slack messages. Requests for laptops had no consistent approval trail, no visibility into fulfillment status, and no reporting on how long onboarding actually took. IT Support had no structured way to track outstanding requests or measure turnaround time.

What I Built

- A “New Employee Laptop Request” Service Catalog item with a laptop model dropdown (MacBook Pro, Dell Latitude, Lenovo ThinkPad), an accessories checkbox field, and a required justification field.
- A Flow Designer approval workflow with dynamic manager-approval routing (dot-walked from the requester's Manager field): trigger on request creation → manager approval → IT fulfillment task → auto-close, with an email notification sent at each stage.
- A custom field on the Incident table (u_auto_priority_source), set via a Business Rule that auto-assigns priority based on category, plus an ACL restricting write access on that field to the itil role — verified visible/editable for IT Support and hidden on the Self-Service view for end users.
- A user/group/role security model with two groups (IT Support, Approvers) and least-privilege role assignments across three test users.
- A two-widget reporting dashboard (“Laptop Request Fulfillment Dashboard”): a bar chart of requests by status (Approved vs. Closed Complete) and a list view of request-level fulfillment timestamps (Opened / Closed) for tracking turnaround time.
- All configuration captured in a single named Update Set, activated before any configuration work began and exported as XML for migration and audit purposes.

Why

This project mirrors a real onboarding workflow that a ServiceNow admin is asked to own: catalog intake, approval routing, fulfillment tracking, and reporting — all built with the same discipline (Update Set hygiene, least-privilege ACLs, tested role-based visibility) expected in a production instance rather than a one-off demo.

Result

A working catalog item that routes from request to fulfillment with a full approval and notification trail, a locked-down custom Incident field verified against two different user roles, and a dashboard giving IT Support real-time visibility into request status and turnaround time. The complete Update Set XML and a walkthrough recording accompany this summary as separate portfolio artifacts.
